

Complex Social Systems: THE BEHAVIOURAL SINK

CSS Project's Presentation -
Alessio Melone, Henrique Ranieri, Francesco Rosano

Materials may not be shared without previous written permission of the authors and DH

Universe 25 Experiment – John B. Calhoun, 1968

SETTING

- Four mice couples at t_0
- «Rat Utopia»:
 - Unlimited food and water
 - Protection from predators
 - Protection from weather
 - Protection from external diseases
- Four pens in a «U» shape, one food dispenser each
- Habitat built for 4000 mice
- Only one scarce resource: **space**

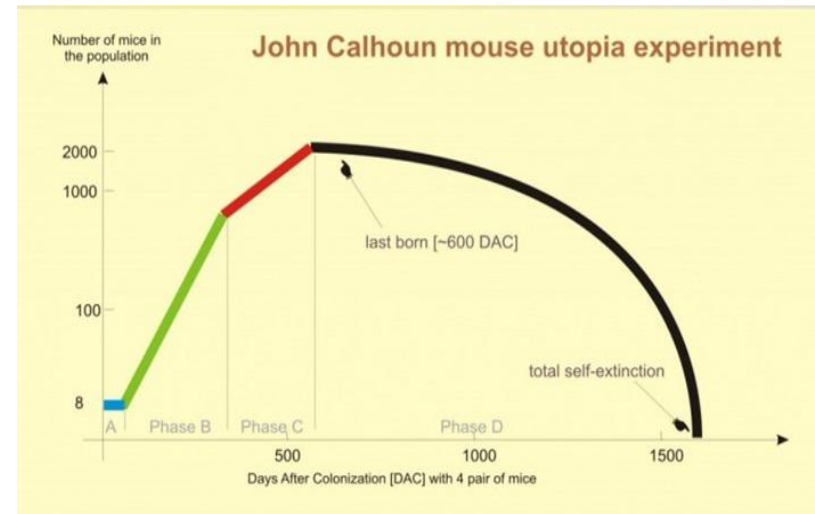

Universe 25 Experiment – John B. Calhoun, 1968

EMERGING BEHAVIOURS

- Population peaked at 2200 mice (habitat for 4000)
- Antisocial emerging behaviour:
 - Mothers abandoning «motherhood», infant mortality
 - Cannibalism
 - Increased aggressivity
 - Sexual deviation
 - Self-isolation/«togetherness» necessity
 - Hyperactivity/laziness
 - Strict social hierarchy
- High density lead to extinction

➡ "BEHAVIOURAL SINK"

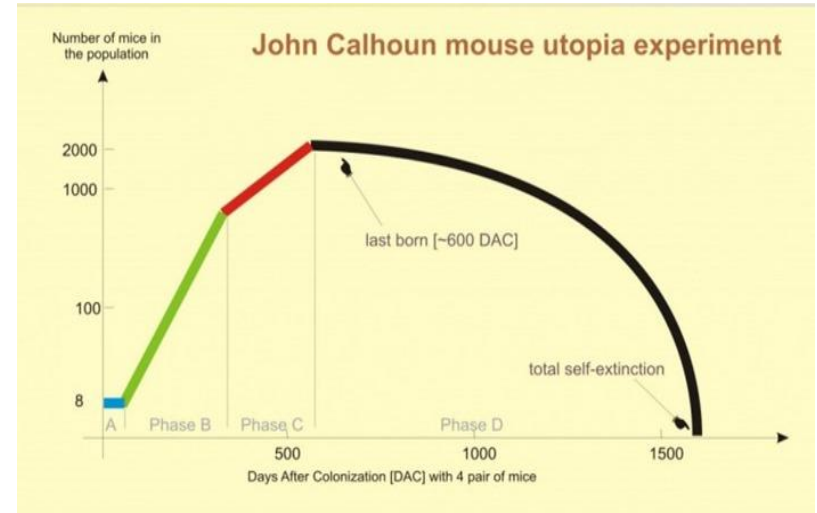

*Too many complex
emerging behaviours for
a single model?*

Universe 25 Experiment – John B. Calhoun, 1968

EMERGING BEHAVIOURS:

- Population peaked at 2200 mice (habitat for 4000)
- Antisocial emerging behaviour:
 - **Mothers abandoning «mothership», infant mortality**
 - Cannibalism
 - **Increased aggressivity**
 - Sexual deviation
 - Self-isolation/«**togetherness**» **necessity**
 - Hyperactivity/laziness
 - **Strict social hierarchy**
- High density lead to extinction

➡ "BEHAVIOURAL SINK"

OUR FOCUS:

Explored using 3 different agent-based models

Agenda

Models

1. Social togetherness
2. Social Dominance and Fights
3. Infant Mortality and Mothership

1. Social togetherness

Speaker: Henrique Ranieri

«Gradually the social aspect of the activity (of eating - editor's note) became determinant: the rats would rarely eat except at hopper already in use by other animals.

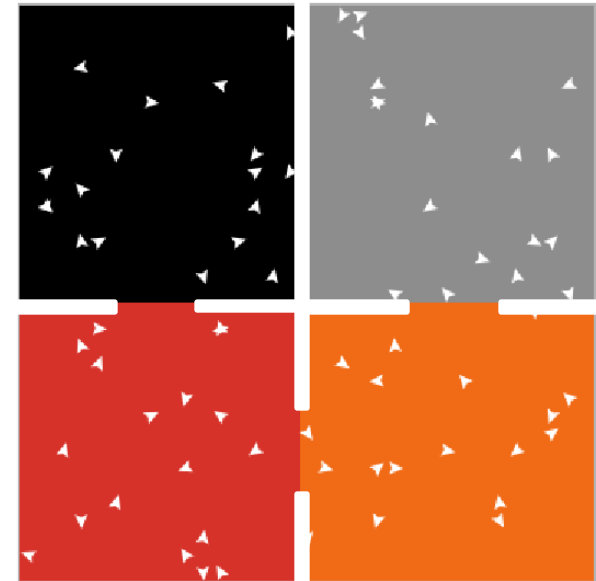

...

the same pathological "togetherness" tended to disrupt the ordered sequences of activity involved in other vital modes of behavior such as the courting of sex partners, the building of nests and the nursing and care of the young

*Population Density and Social Pathology,
John B. Calhoun*

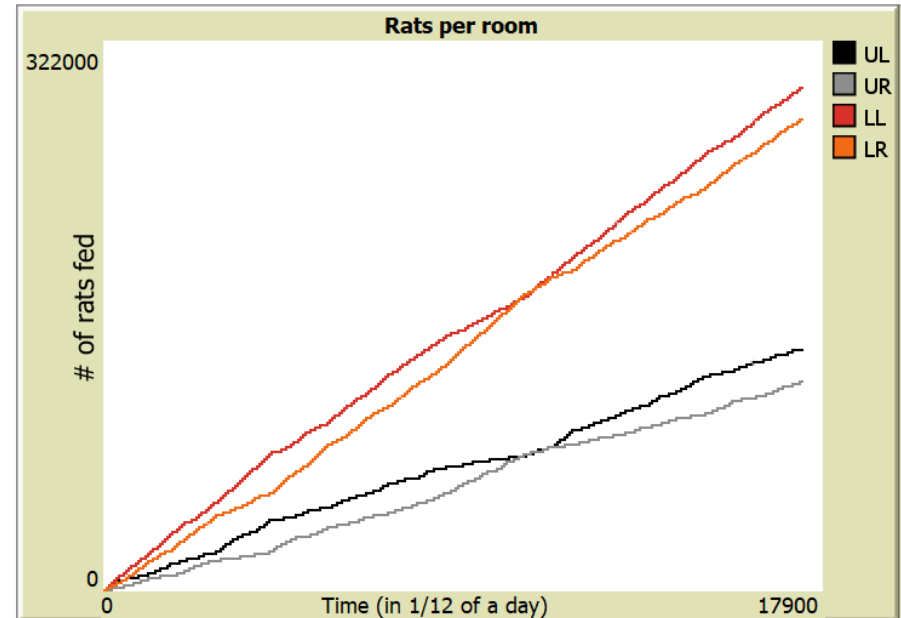

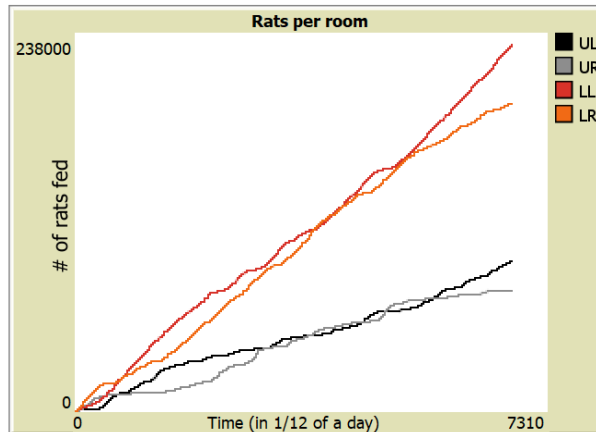

Social togetherness - Model

- Focus: "Eating and other biological activities were thereby transformed into social activities in which the principal satisfaction was interaction with other rats."
- Environment:
 - Four rooms with three bridges in between.
- Agent behaviour:
 - Each rat tries to feed on a unique feeding window. Fixed size, random interval.
 - Prioritize adjacent rooms that meet their social togetherness necessities.
 - Social togetherness dynamically changes with the amount of rats each specific rat ate with. Eating with more rats conditions the rat to seek more social togetherness.
- Generational dynamic: Rats die and new ones are born. Always constant population size.

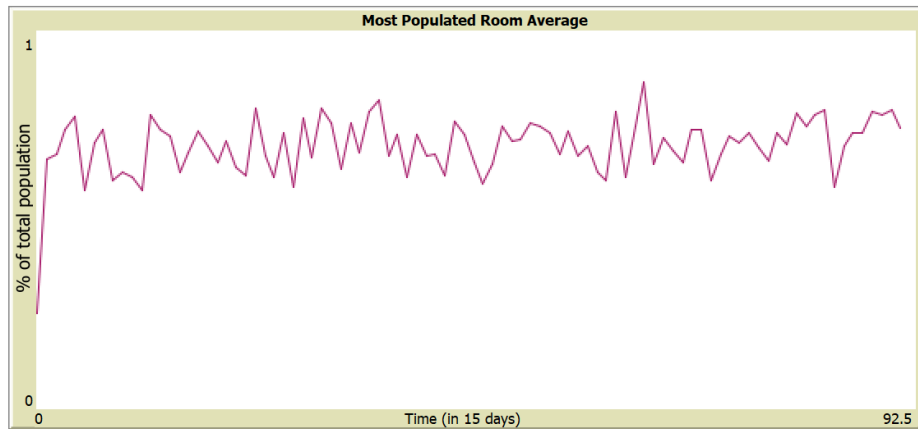

Social Togetherness - Population distribution

- Lower rooms are consistently more populated.
- Total room population emerges in vertical pairs.
 - Self-reinforcing social hub.

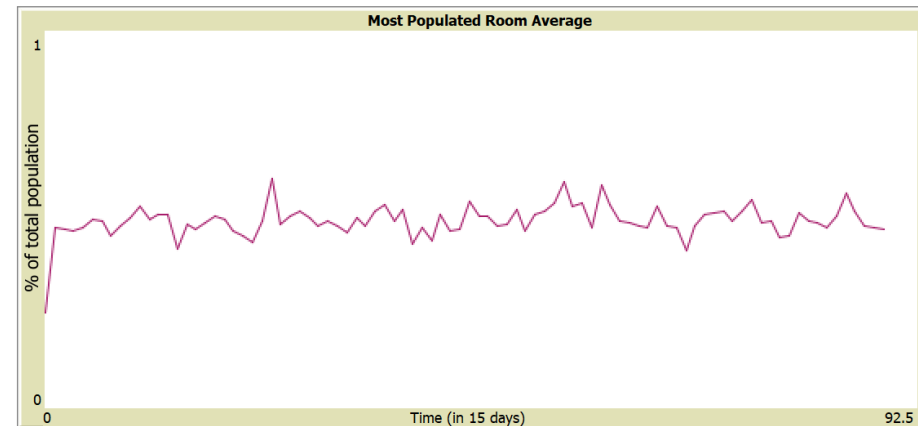

Social Togetherness - Beneficial environment conditions

- The ease of environmental conditions allows social behaviours to thrive, leading to clustering.
 - More flexible feeding time.
 - More food available.

feeding windows of size 90% of the day

feeding windows of size 25% of the day

Social Togetherness - Additional observed behaviors

- New generations have little influence over an established environment.
- Conditioning coefficient values become irrelevant over time.

2. Social Dominance and Fights

Speaker: Alessio Melone

«... a dominant male was usually able to expel all other males and possess a harem of females. The sex ratio approximated equality only in those groups that fell within the expected size range. In the larger groups, on the other hand, there were many more males than females.

...

The more fights a male initiated and the more fights he won, the more likely he was to establish a position of dominance.

*Population Density and Social Pathology,
John B. Calhoun*

Social dominance and fights

Social dominance and fights – Mouse attributes

- **sex** : Mice can be male ("M") or female ("F").
- **energy** : Represents the health of a mouse. A mouse dies if its energy goes to 0. It is decreased at every tick and in case of fight, the winner has a lower decrease than the loser.
- It is necessary for females in order to give birth (they only mate if their energy is higher than 50% of the maximum energy. Can be brought back to **max-energy** when eating.
- **age** : Increases each tick, influences fertility (a mouse is considered fertile in a certain range of age).
- **social-status** : For males, a value between 0 and 1 indicating dominance. Affects the probability of winning fights and a mouse is considered dominant and marked in red if its social-status goes over a certain threshold **dominance-threshold**.
- **behavior** : Can be "normal" or "beautiful", affecting movement and interactions. Setting **behavior-change-probability** to 0 allows not to take behavioral change to "beautiful" into account, made for simplicity.
- **Reproduction**: Females can become pregnant and give birth after a gestation period.

Social dominance and fights – Model parameters

- **initial-population** of mice. **Changing** in analysis.
- **max-age** and **death-probability-factor** : after a certain age, the mice start dying with a probability proportional to the exceeding and the death probability factor. Both fixed for simplicity.
- **max-energy** and **energy-loss-rate** are fixed for simplicity and indicate respectively the maximum energy and the energy lost per tick by each mouse.
- **overpopulation-threshold** indicates the number of mice present in a radius of 5 from a certain mouse or patch to be considered overcrowded.
- **pregnancy-duration** , **min-offspring** and **maximum-offspring** for each birth.
- **dominance-threshold** is the threshold after which a mouse is considered dominant by other mice. **Changing** in analysis.
- **fight-probability-factor** affects the probability of males fighting when overcrowded. Setting it to 1, we force the male mice to fight whenever it's overcrowded.

Social dominance and fights – Moving

Seeking Food:

- **Dominant Males:** Claim and hover around a dispenser.
- **Non-Dominant Males:** Avoid dispensers near dominant males.
- **Females:** Go to the nearest dispenser.

Seeking Mates: appx. 5 attempts per lifespan.

- **Dominant Males:** Avoid mating if stronger males are nearby.
- **Non-Dominant Males:** Avoid females near dominant males.

Random Movement: Bias towards the center when idle.

Social dominance and fights – Mating and fighting

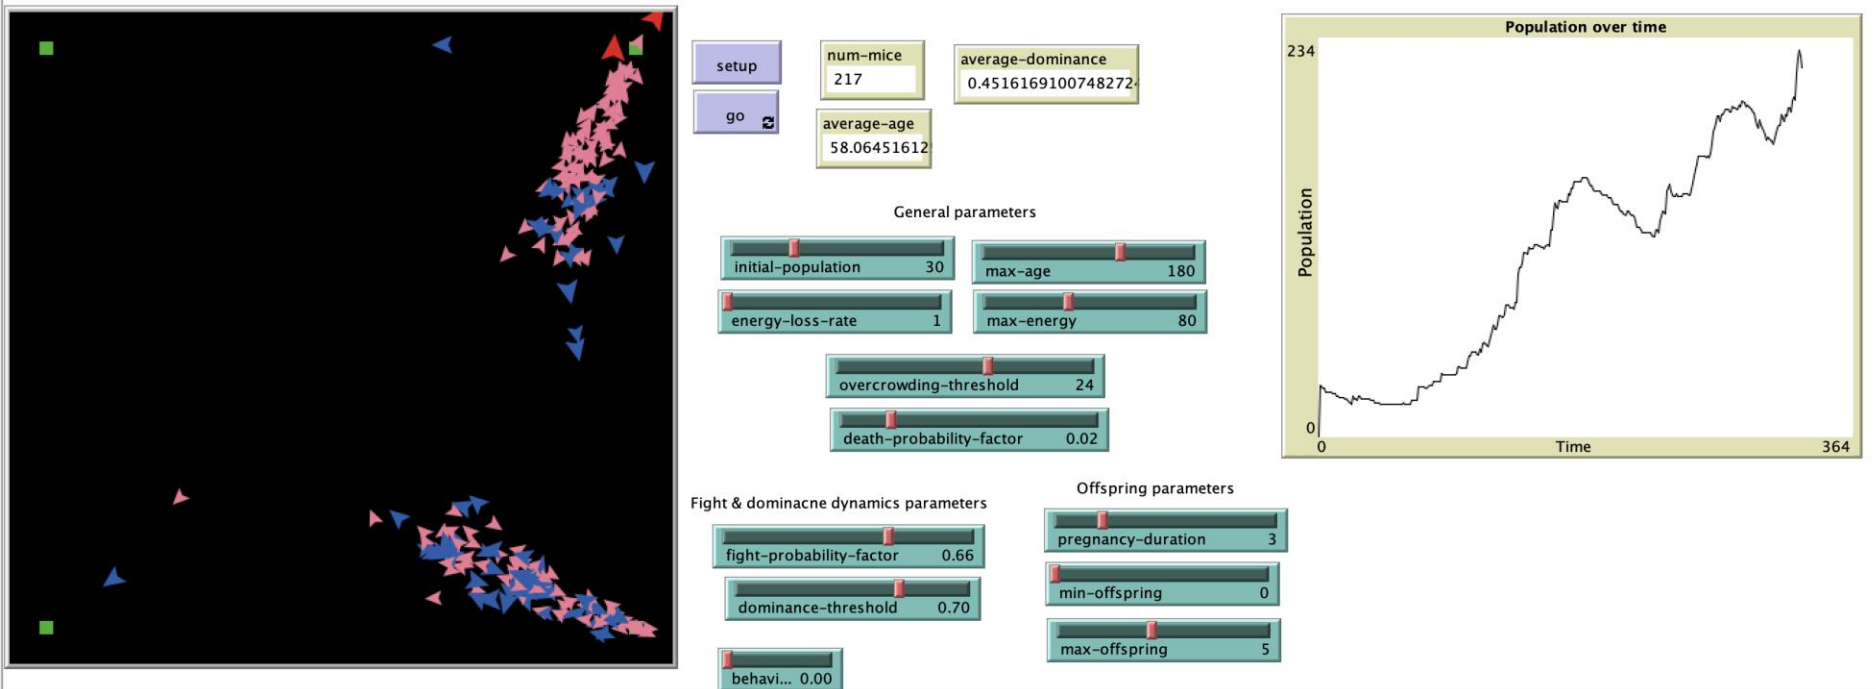

Fighting

- Happens among males under overcrowded conditions.
- Outcomes depend on social status and energy; can lead to death.

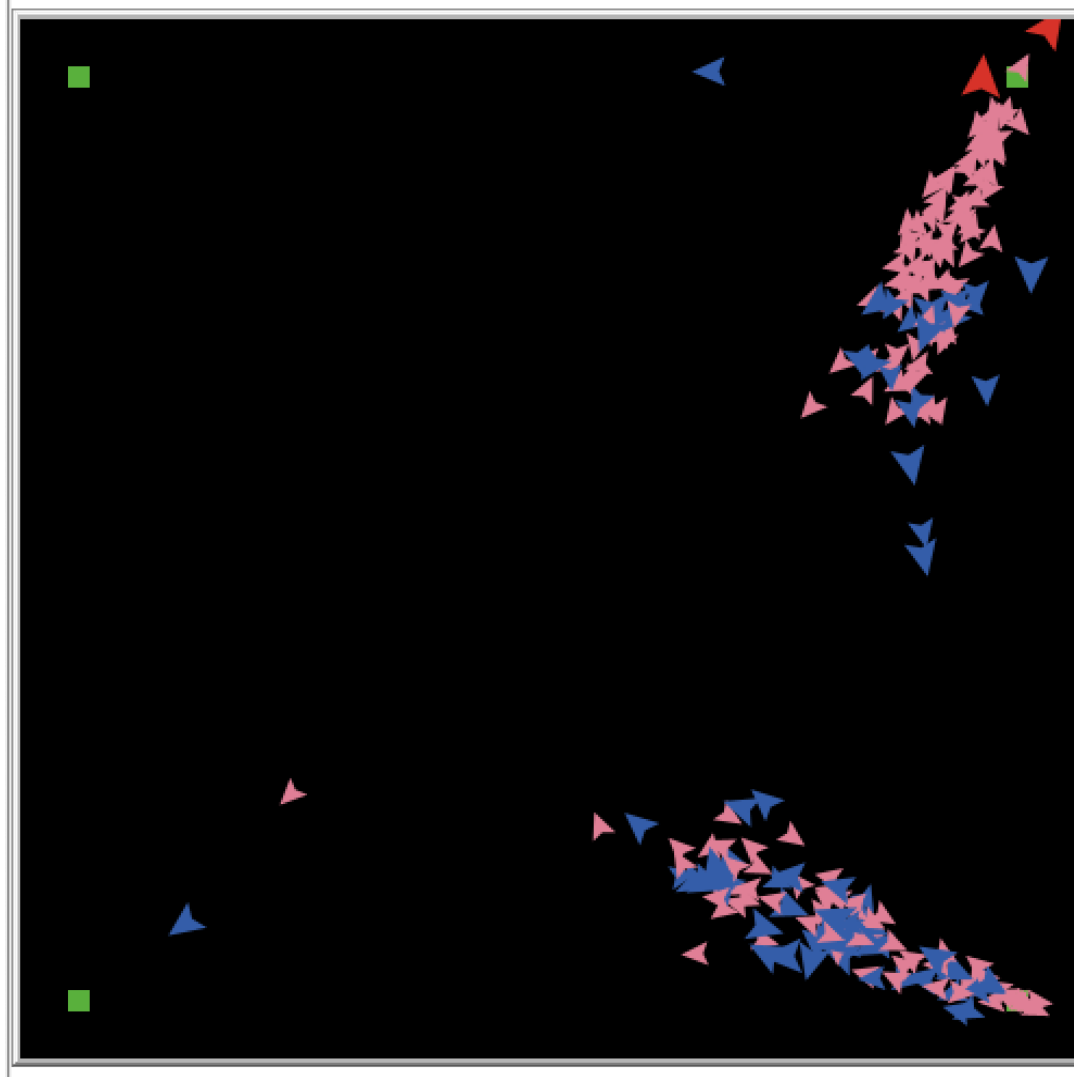

Reproducing

- Fertile females reproduce based on energy and overcrowding.
- After gestation, they give birth to a random number of offspring.

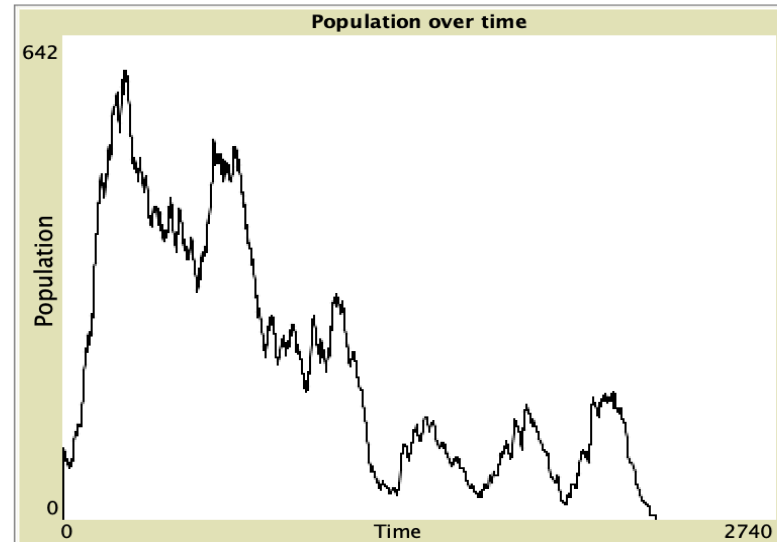

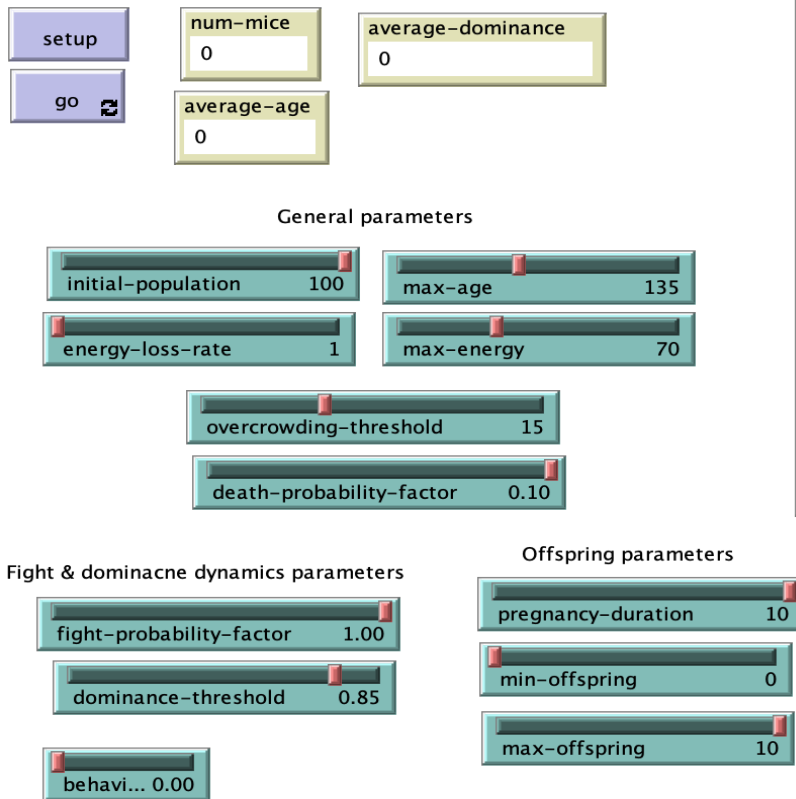

Social dominance and fights – Clustering

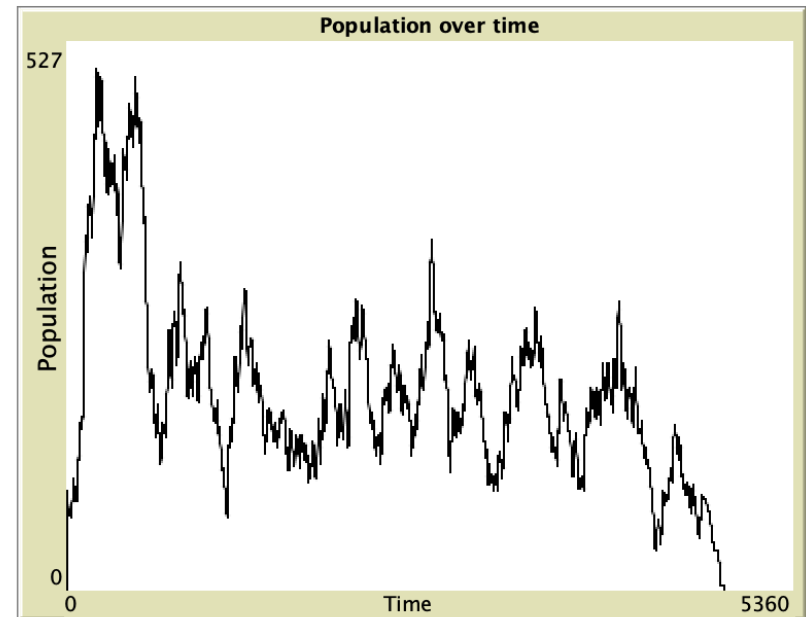

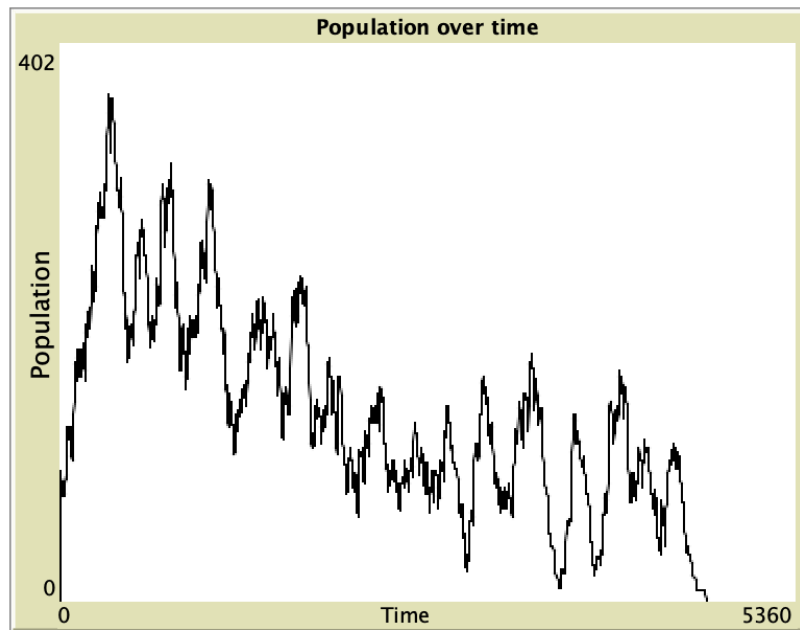

Social dominance and fights – Clustering

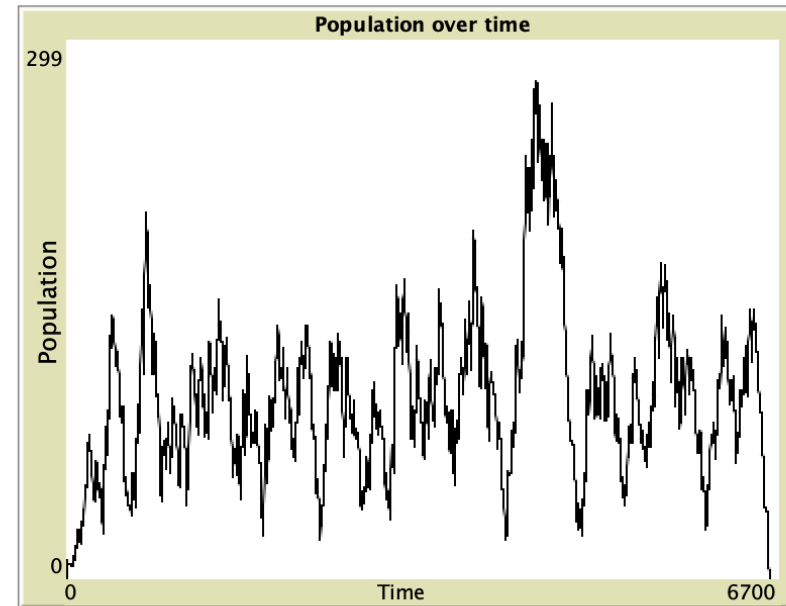

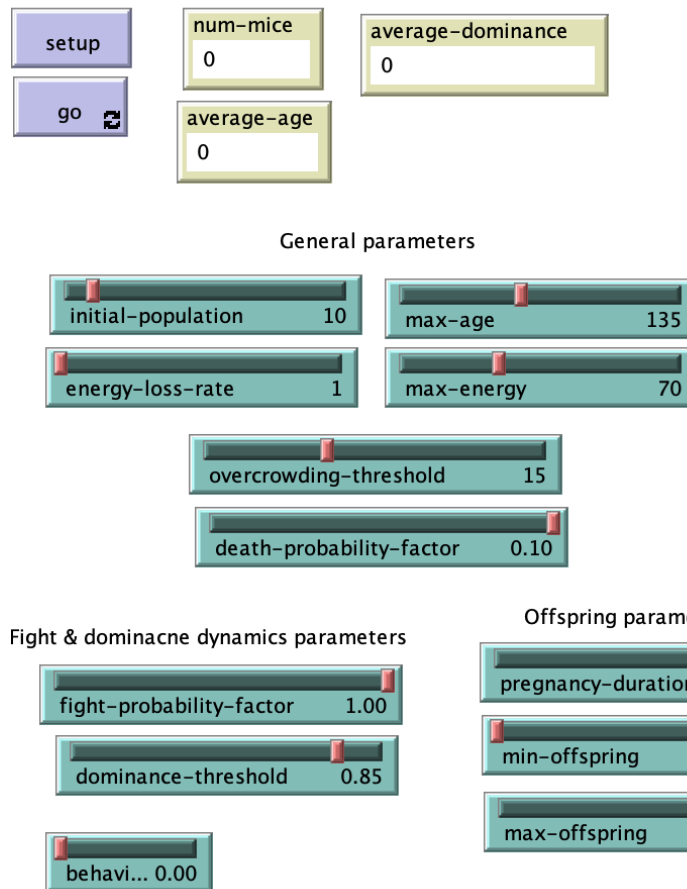

Social dominance and fights – 100 initial population

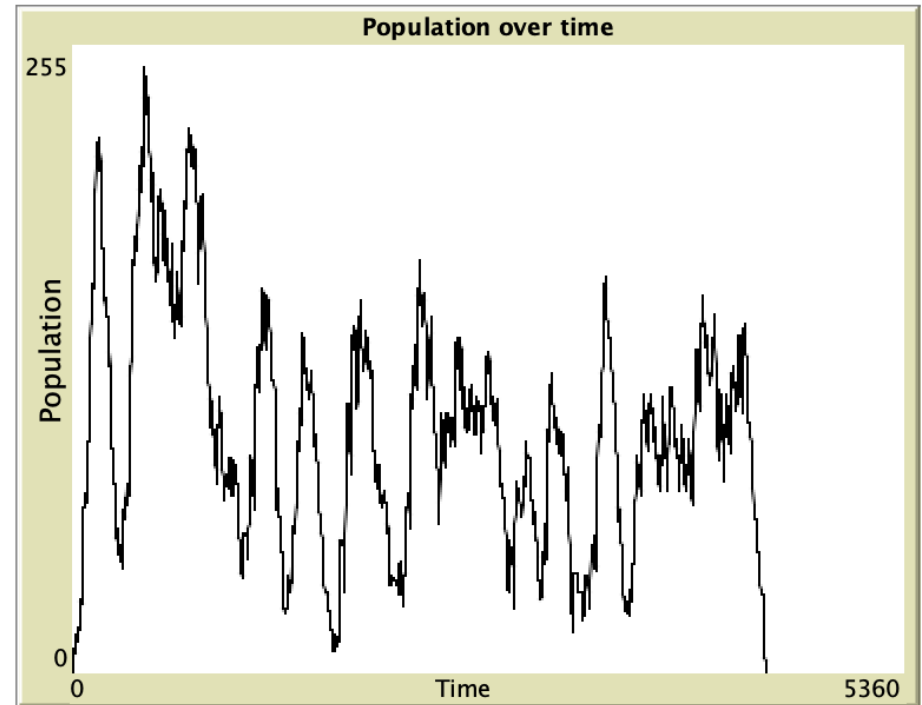

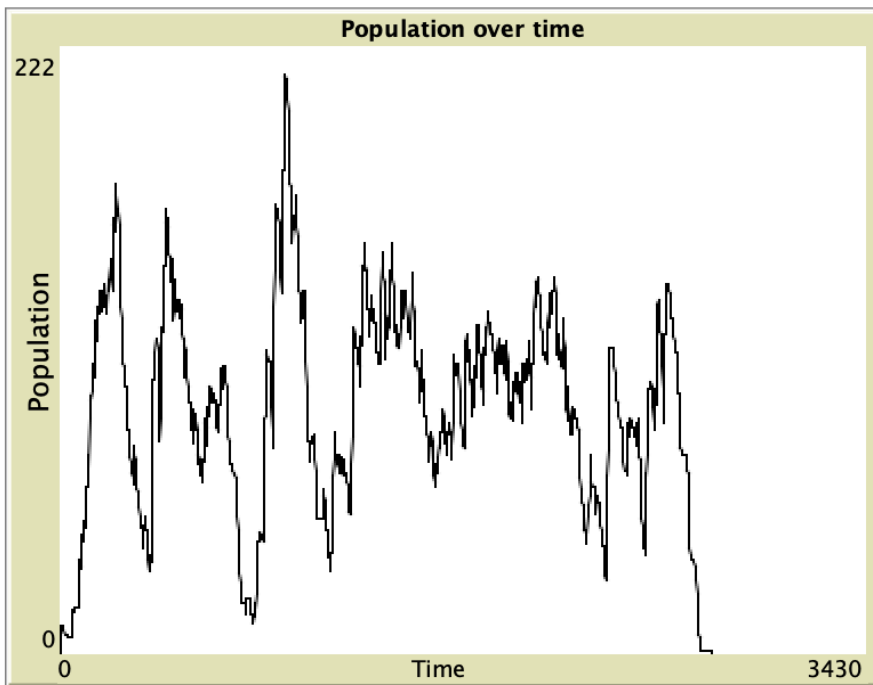

Social dominance and fights – 100 initial population

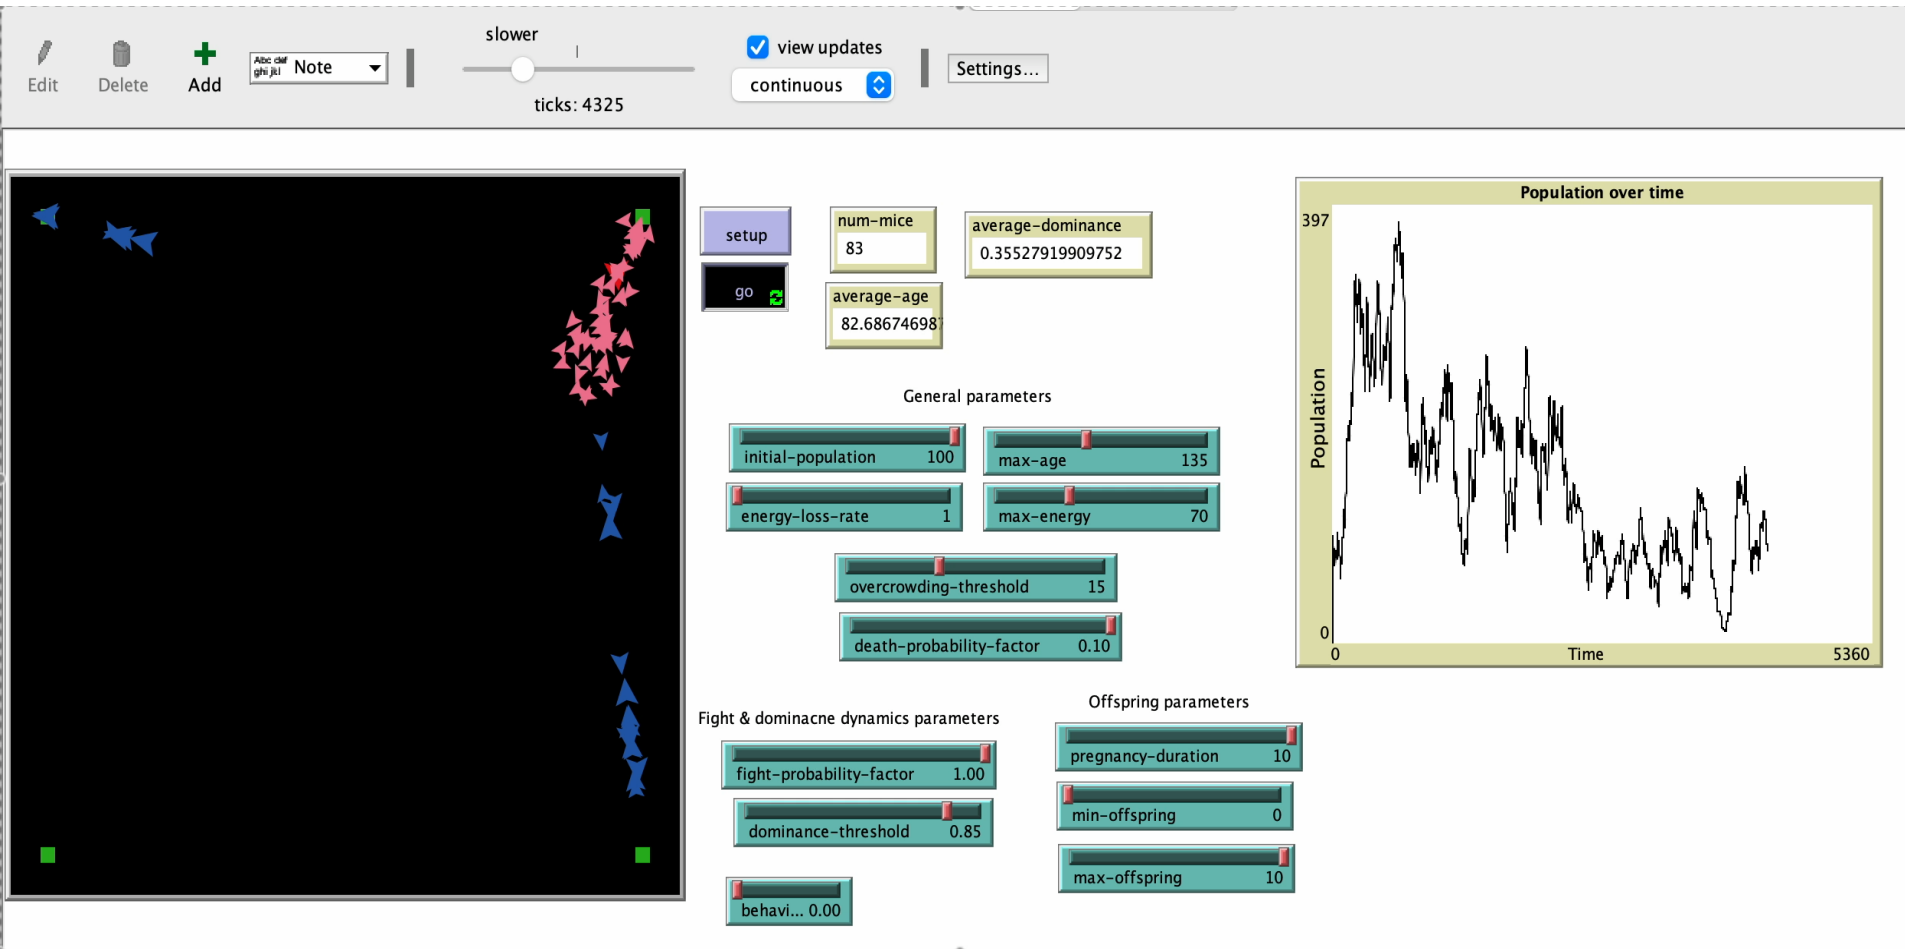

Social dominance and fights – 10 initial population

Social dominance and fights – 10 initial population

Social dominance and fights – Why extinction?

Social dominance and fights – Changing max-age

num-mice: 0
 average-dominance: 0
 average-age: 0

General parameters

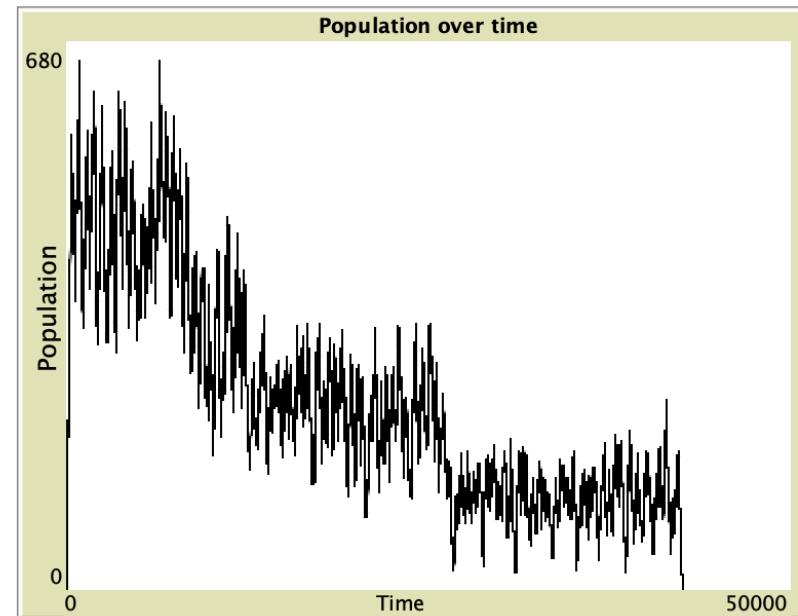

initial-population: 100
 max-age: 250
 energy-loss-rate: 1
 max-energy: 70
 overcrowding-threshold: 15
 death-probability-factor: 0.10

Fight & dominance dynamics parameters

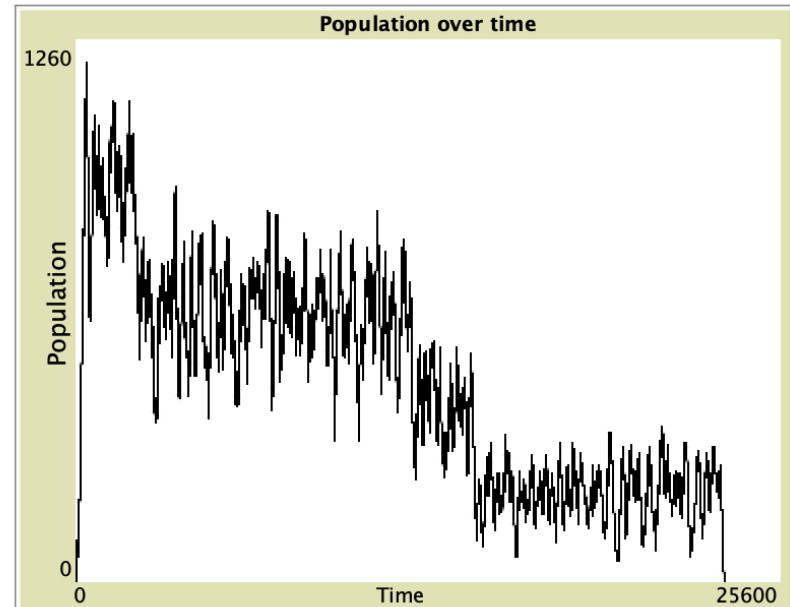

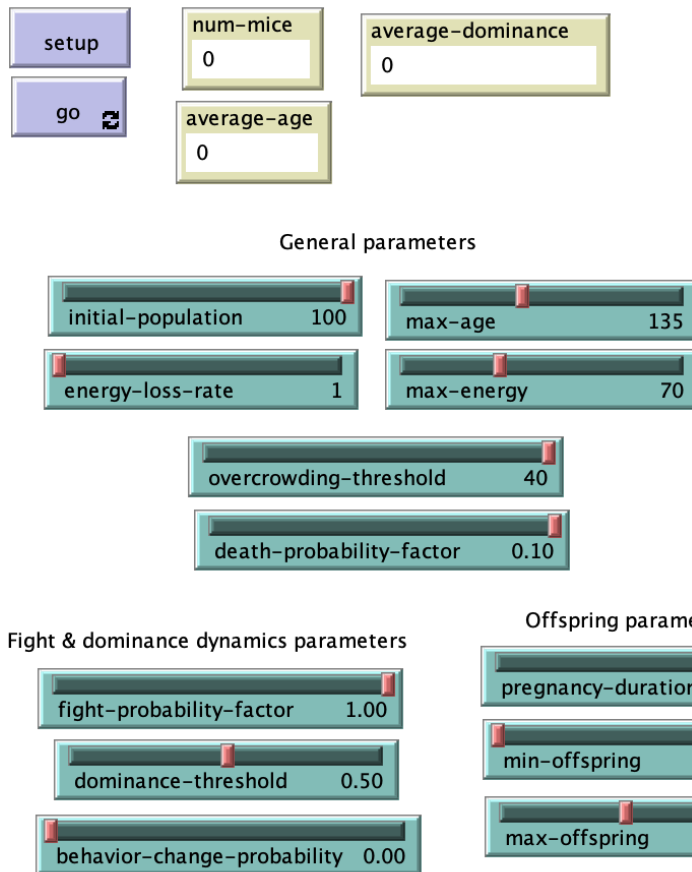

fight-probability-factor: 1.00
 dominance-threshold: 0.50
 behavi... 0.00

Offspring parameters

pregnancy-duration: 10
 min-offspring: 0
 max-offspring: 10

Social dominance and fights – Changing Overcrowding Threshold

3. Infant Mortality and Mothership

Speaker: Francesco Rosano

«... An even greater number (of females - editor's note), after successfully giving birth, fell short in their maternal functions.

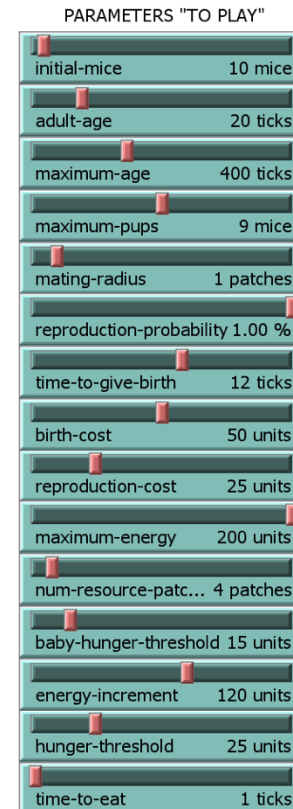

... stress from social interaction led to such disruption of maternal behavior that few young survived.

*Population Density and Social Pathology,
John B. Calhoun*

Infant Mortality and Mothership

MODEL RULES:

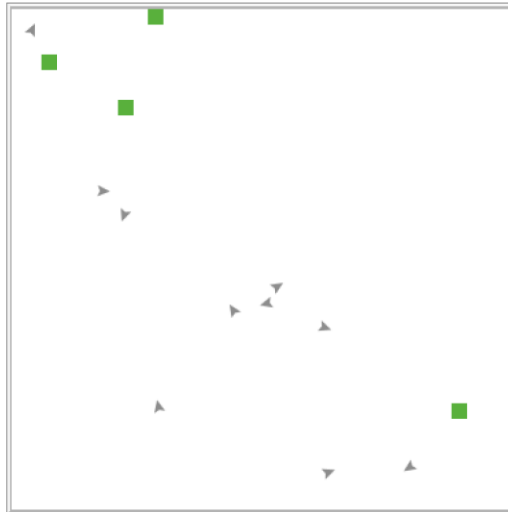

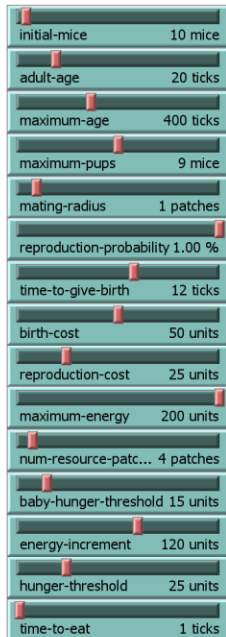

- Finite number of infinite energy sources
- Agents move randomly until when they need resources, then towards sources
- Time to eat proportional to the number of agents in the radius of the source
- Only «adult» mice get pregnant (coupling with another mouse)
- Pregnancy takes time
- «Young» mice can get fed only by their parents

Infant Mortality and Mothership

MODEL SETTING:

PARAMETERS "TO PLAY"

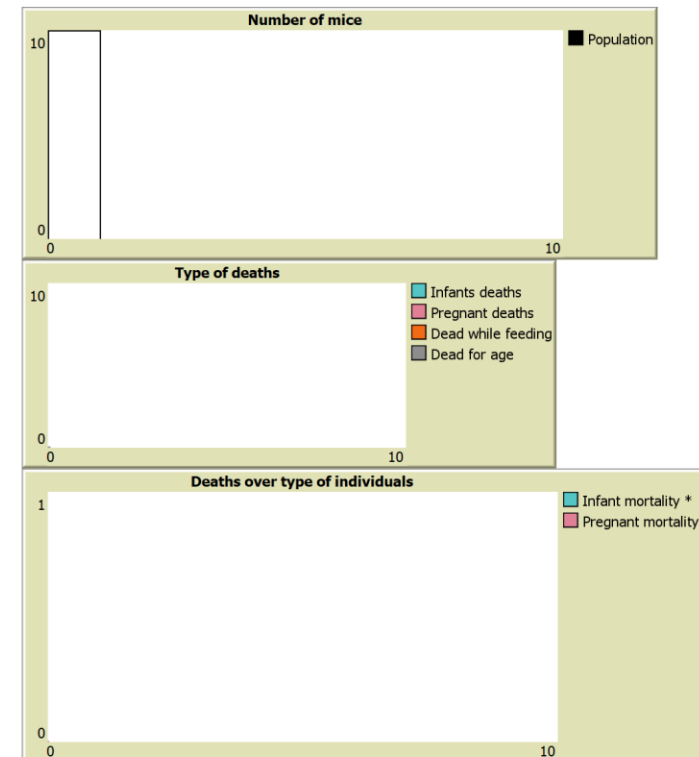

setup

go

go 2

MAIN
PARAMETER

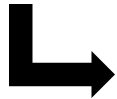

Infant Mortality and Mothership

LOW «MOTHERSHIP»

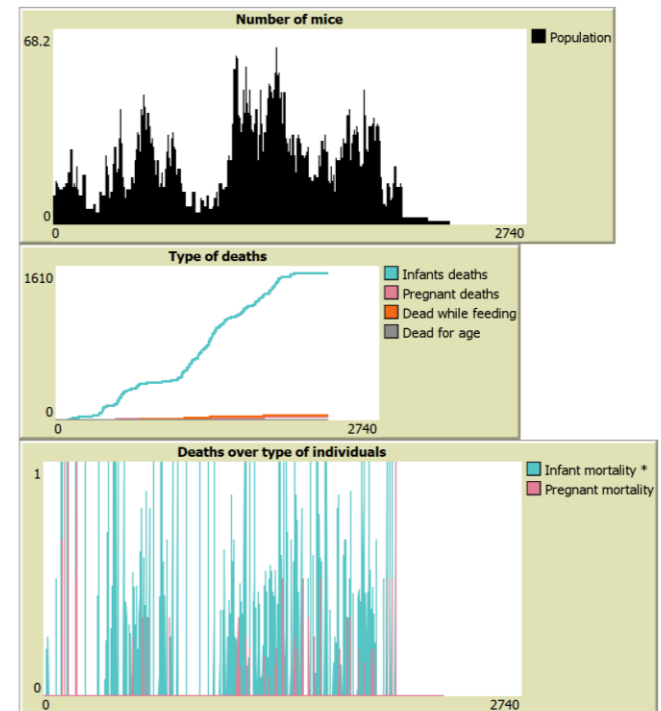

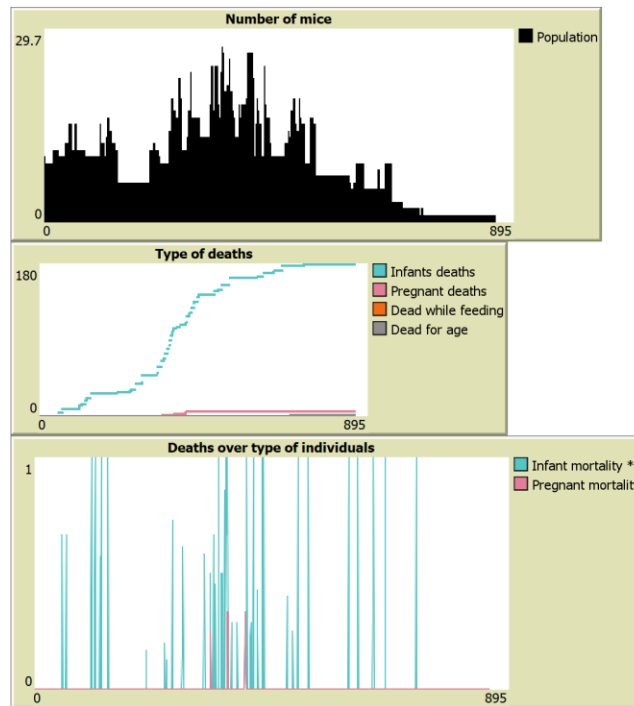

EXTINCTION

VERY LOW
PEAKS OF
POPULATION

parenting-energy-lower-bound 60 units

CORRELATION BETWEEN POPULATION PEAKS AND INFANT MORTALITY

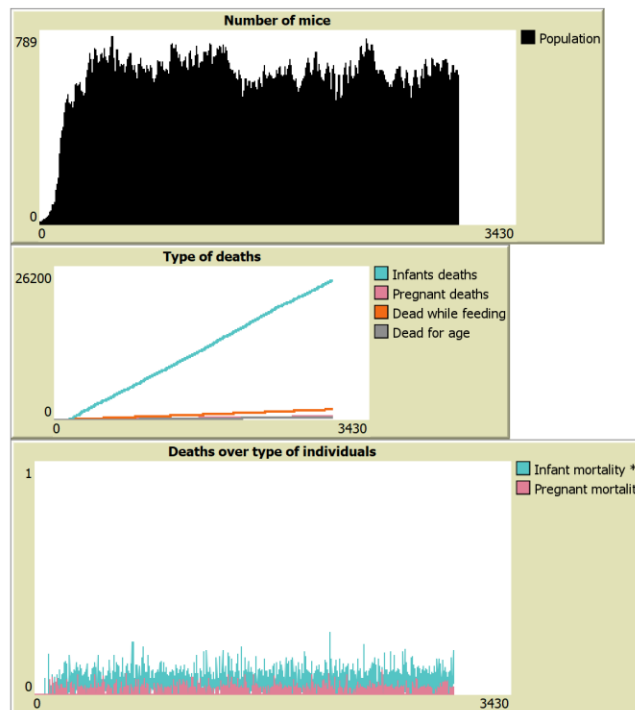

Infant Mortality and Mothership

HIGH «MOTHERSHIP» → STABILITY

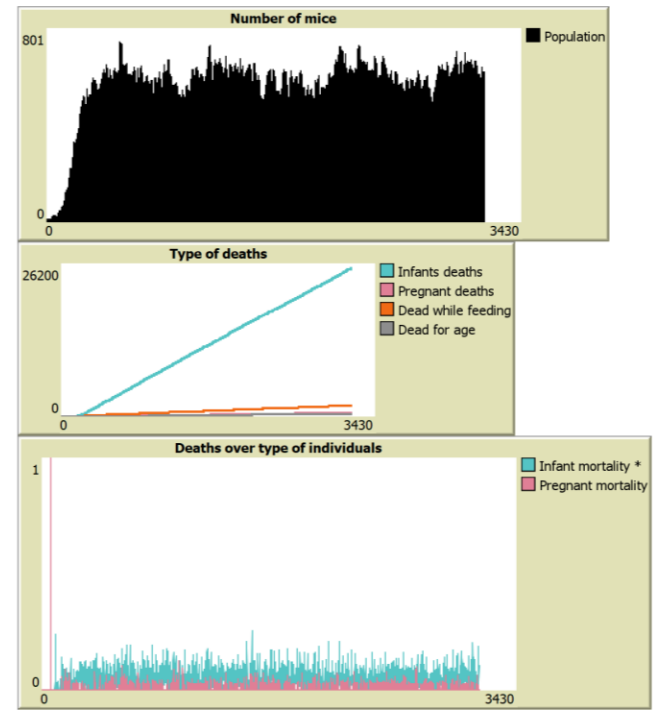

AVERAGE
POPULATION IS
WAY HIGHER

parenting-energy-lower-bound 20 units

INFANT MORTALITY IS STABLE, AND OVERALL LOWER

Thank you for your attention!
